A recent development in the study of latent variables is growth mixture models (GMMs). Masyn, Henderson, and Greenbaum (2010) organized factor mixture models (FMMs) along a dimensional categorical spectrum, with factor analysis, a dimensional model, at one end and latent class analysis at the other. GMMs are special cases of the FMM with repeated measures and growth parameterizations.

This chapter gives an overview of recent advances in latent variable analysis. Emphasis is placed on the strength of modeling obtained by using a flexible combination of continuous and categorical latent variables. To focus the discussion and make it manageable in scope, analysis of longitudinal data using growth models will be considered.

Latent variable mixture modeling is an emerging person-centered statistical approach that models heterogeneity by classifying individuals into unobserved groupings (latent classes) with similar (more homogenous) patterns. The purpose of this article is to offer a nontechnical introduction to cross-sectional mixture modeling.

the continuous latent variables appear in the form of random effects describing individual differences in development over time. The categorical latent variable column includes cross-sectional models such as latent class analysis (LCA), which in longitudinal settings generalizes to latent transition analysis (LTA).

Mixture regression — a type of finite mixture model/latent class analysis — is a method to examine whether the relationships between independent and dependent variables differ for latent classes. That is, mixture regression identifies classes for whom the relationships between the independent and dependent variables differ.

Finite mixture factor analysis provides a parsimonious model to explore latent group structures of high dimensional data. In this modeling framework, latent structures can be specified for continuous responses. However, dichotomous items are often used to define latent domains in practice.

When estimating finite mixture models, it is common to make assumptions on the mixture components, such as parametric assumptions. In this work, we make no distributional assumptions on the mixture components and instead assume that observations from the mixture model are grouped, such that observations in the same group are known to be drawn from the same mixture component.
